Phentermine is a prescription medication that belongs to a class of drugs known as sympathomimetic amines, which act as appetite suppressants. It is primarily prescribed as a short-term aid to weight loss in adults who are overweight or obese and have not been able to lose weight with diet and exercise alone. Phentermine is designed to be used as part of a comprehensive treatment plan that includes calorie control, physical activity, and behavioral changes.

## How Phentermine Works

Phentermine works by stimulating the release of certain brain chemicals, including norepinephrine, which reduces hunger signals and increases alertness and energy expenditure. This effect helps individuals eat less and maintain motivation while following a structured weight-loss plan.

Because Phentermine acts as a stimulant, its effects are similar to those of amphetamines but at much lower, medically monitored doses.

## Medical Uses of Phentermine

Phentermine is approved for short-term treatment of obesity (generally a few weeks) in adults with a body mass index (BMI)  $\geq 30$ , or  $\geq 27$  if other weight-related conditions such as diabetes, hypertension, or high cholesterol are present.

### 2. Combination Therapy:

In some cases, Phentermine is prescribed with other medications (such as topiramate) for long-term weight management under strict medical supervision.
